OpenAI Board Review / March 9, 2026

Asolaria is what a frontier-model operating substrate already looks like in the wild.

Not a chatbot shell. Not a single agent.

A governed local-first control plane with Codex, Symphony, remote MCP, graph telemetry, memory, mistakes, desktop action, phone action, and relay-backed multi-machine coordination.

The Core Claim

The interesting artifact is not the interface. It is the operating spine.

What is already integrated:

- Codex in the primary provider chain
- Symphony as a managed long-running sidecar
- Remote MCP used as compact integration fabric
- Desktop, browser, voice, and phone lanes
- Persistent project, memory, and mistake stores
- Graph runtime with typed events and action manifests

Live Surface Area

This is already a substantial operational system.

40 connector modules

53 indexed skills

32 indexed tool actions

5 tracked project scopes

Worker lanes: local_codex, abacus, symphony

Governance

The system treats tool use as governed infrastructure.

- explicit authority modes
- two-step authority transitions with rollback
- approval-bound tool execution
- readiness drills
- audit verification that can lock writes on failure

OpenAI-Native Lanes

Codex, Symphony, Linear, and voice are already operating lanes.

- Codex anchors the provider chain and the highest-trust local engineering lane
- Symphony is repo-aware, workflow-aware, and Windows-aware
- Linear is part of issue pickup and workflow routing
- Voice defaults to gpt-4o-mini-transcribe

Cloud and Context

GCP, Vertex, NotebookLM, and Augment are integrated with restraint.

- service-account backed GCP with allowed-project enforcement
- Vertex daily request and token budgets
- NotebookLM-ready cloud posture
- Augment/Auggie as a read-only codebase-retrieval sidecar

Actuation

This system already reaches beyond software-only agency.

- desktop capture, control, and display
- browser and WebMCP workflows
- phone mirror, browser history, developer options, and recovery lanes
- operator-assist paths such as AnyDesk monitoring

Graph Layer

The graph runtime is live now, and the GNN posture is mature because it is honest.

- typed graph events and action manifests
- edge-risk scoring at event build time
- graph-runtime training dataset export
- no evidence of GNN inference in the hot path yet
- policy and approvals remain the root of trust

Multi-Machine Fabric

The system scales outward through relay, watchdog, and bootstrap patterns.

- room-based relay with auth, allowlists, and sender tokens
- watchdog restart and identity enforcement
- cross-host bootstrap materials for new workstations
- friend-machine path that can adapt the control plane onto another Mac or PC

Board Takeaway

The next important layer is not a better prompt box.

It is the governed operating system around frontier models.

Asolaria shows the shape: Codex, Symphony, remote MCP, graph telemetry, authority, memory, mistakes, and actuation in one auditable fabric.
