Subject: Asolaria package for OpenAI board presentation

John,

I am sending you a board-facing package on Asolaria for your presentation to the OpenAI board because I think it captures something strategically important about where frontier-model systems are heading.

Asolaria is not a chat wrapper and not a single-agent shell. It has become a local-first control plane that combines frontier-model reasoning, governed tool execution, Codex as a primary execution lane, Symphony as a managed workflow sidecar, compact remote MCP integration, graph-native runtime telemetry, persistent memory and mistake capture, and desktop plus phone actuation inside one operator-facing system.

What I think is most important for the OpenAI board is not just the breadth of features. It is the architecture. The system already separates reasoning, execution, governance, actuation, and recovery in a way that looks much closer to how serious users actually want to operate frontier models. It treats authority, approvals, audit, routing, and failure recovery as first-class runtime concerns rather than afterthoughts.

The attached package is structured to make that case clearly:

- a concise board memo
- a deeper system card
- a citation-heavy system card companion
- a narrative deck version

The graph layer is an especially relevant technical signal. Asolaria already records typed graph events and action manifests and can export training data from real runtime windows. Just as important, the current posture is disciplined: the graph substrate is live, but there is no claim that GNN inference is already in the hot path. Policy and approvals remain the root of trust. That is the right way to integrate advanced graph learning into a live agentic control plane.

My view is that Asolaria is worth attention not because it is finished, but because it reveals the shape of the next layer. The important opportunity is not another chatbot shell. It is the governed operating system around frontier models: local execution, durable workflow lanes, compact tool integration, auditable authority, and telemetry rich enough to support future model-assisted control.

I wrote this package to support that exact frame: not "look at my app," but "look at the operating substrate serious users are already building around frontier models."

Thank you for putting it in front of the board.

Jesse
